Executable Files and Run Instructions

Trip Planner — Supporting Project Document

Prerequisites

Install Python, Node.js with npm, and Git. Obtain valid provider credentials and configure them privately on the backend.

Backend Setup

Open a terminal in backend/. Create or activate a Python virtual environment, install dependencies with pip install -r requirements.txt, and configure the local .env file. Run uvicorn main:app --reload --port 8000 from the backend directory.

Frontend Setup

Open another terminal in frontend/. Run npm install, then npm run dev. Open the local URL printed by Vite. Keep both frontend and backend processes running.

Configuration

Use the API base/proxy configuration appropriate for local development or deployment. Do not put privileged Groq or Supabase keys in frontend variables.

Troubleshooting

If requests fail, inspect terminal output, API URL/proxy settings, port conflicts, environment variable names and database schema. Never share secret values in screenshots.
